1. Introduction

The results of this talk follows on my papers [F,JSL] and [F,AM], where it was shown that each binary string α which is complex (random) in the sense of Kolmogorov-Chaitin (a *KC*-string) can be algorithmically transformed into a “generic” Brownian motion x_α .

It is generic in the sense that every probabilistic event which holds almost surely with respect to the Wiener measure, is reflected in x_α , provided the probabilistic event has a suitably effective description.

2. Complex oscillations

The class of generic Brownian motions coincides with a class \mathcal{C} of functions which were introduced by Asarin and Prokovskiy in 1986.

Each function in the latter class is a uniform limit of a sequence (x_n) of piecewise linear functions.

Moreover, every x_n can be encoded by a binary string s_n of length n such that, for some positive constant d , the Kolmogorov complexity of s_n is at least $n - d$, for all large values of n .

For this reason we called the elements of \mathcal{C} *complex oscillations*. The complex oscillations have interesting recursion-theoretic properties. For example, it is shown in [F,JSL] that, if x is a complex oscillation and r is a nonzero recursive real number in the unit interval, then $x(r)$ will not be a real number. In [F, AM] I showed that, for each $x \in \mathcal{C}$, one can compute from the values of x at the rational numbers a unique *KC*-string α such that $x = x_\alpha$.

3. Homogeneous structures given by generic Brownian motion

In this way one can identify interesting implicit structure in a generic Brownian motion.

For example, the codes of many countable homogeneous relational structures can be computed from the values of a generic Brownian motion at the rationals in the unit interval. Recall that a relational structure X is homogeneous if any isomorphism $f : A \rightarrow B$ between finite substructures of X can be extended to an automorphism of X .

The universal procedure which computes from the values of a complex oscillation x the KC -string α such that $x = x_\alpha$, also yields a code of a very interesting homogeneous structure, the so-called Rado graph or random graph.

Indeed, if α is a KC -string and e_1, e_2, \dots is a recursive enumeration, without repetition, of the 2-element subsets of ω , let $R_\alpha = (\omega, E_\alpha)$ be the graph defined by:

$$e_i \in E_\alpha \leftrightarrow \alpha_i = 1.$$

Then the graph R_α is isomorphic to Rado's graph [F, 1996].

In this sense one could say that a Rado graph is “enfolded” in every complex oscillation.

6. Recursive properties of rapid points

In the paper on which this talk is based, we take a closer look at the reverse process, namely the unfolding of KC -strings, not only to a generic Brownian motion as in [F,AM], but also to the dynamical aspects of Brownian motion, as reflected in every complex oscillation. Our focus is on the structure of the so-called rapid points of a complex oscillation. The fractal geometry of a

4. Rapid points

Call a point $t \in (0, 1)$ a *rapid point* of a continuous function X on the unit interval when

$$\overline{\lim}_{h \rightarrow 0} \frac{|X(t+h) - X(t)|}{\sqrt{|h| \log(1/|h|)}} > 0.$$

Denote the set of rapid points of X by $R(X)$. It was shown by Orey and Taylor (1974) that Brownian motion has almost surely a set of rapid points of Hausdorff dimension 1.

- 5. Fractal properties of rapid points**
6. Recursive properties of rapid points

4. Fractal properties of rapid points

When X is one-dimensional Brownian motion, the set $R(X)$ has an extremely interesting structure. For example, Kaufmann showed in 1974 that, almost surely, $R(X)$ contains, for each $0 < \beta < 1$, a Salem set of Hausdorff dimension β .

(Recall that a compact subset E of \mathbf{R}^d of Hausdorff dimension $\beta > 0$ is said to be a Salem set, if β is the supremum of the reals $0 \leq \alpha < d$ for which there is some positive nonzero Radon measure μ with support contained in E , such that the Fourier transform $\hat{\mu}$ of μ satisfies $|\hat{\mu}(\xi)|^2 \ll |\xi|^{-\alpha}$, for all large values of $|\xi|$. In this case, E will generate \mathbf{R}^d as an abelian group!)

6. Recursive properties of rapid points

The rapid points of a complex oscillation have a specific recursive structure. If x is a complex oscillation, then x has a dense set of rapid points.

If x is the complex oscillation x_α associated with the KC -string α , a dense set of rapid points can be effectively retrieved from α . *Indeed, there is a universal algorithmic procedure which, upon having access to an oracle for a KC -string α , will yield, for any closed dyadic interval I , a sequence (t_k) of rational numbers in I such that $|t_{k+1} - t_k| < 2^{-k}$ for all $k \geq 1$ and, moreover, such that the limit t of the sequence (t_k) is a rapid point of the complex oscillation x_α associated with α .*

4. Rapid points
5. Fractal properties of rapid points
6. Recursive properties of rapid points

Furthermore, each rapid point of a complex oscillation is *not* a recursive real number.

In fact, if $t \in (0, 1)$ is a recursive real number, then t is an “ordinary” point of x . This means that Khintchine’s law of the iterated logarithm is reflected in x at every recursive t , i.e., if t is recursive, then

$$\overline{\lim}_{h \rightarrow 0} \frac{|x(t+h) - x(t)|}{\sqrt{2|h| \log \log(1/|h|)}} = 1.$$

6. Recursive properties of rapid points

Briefly the construction of x_α from a KC -string α is as follows:
Let $g : (0, 1) \rightarrow \mathbf{R}$ be the function defined by

$$\alpha = \int_{-\infty}^{g(\alpha)} \frac{e^{-t^2/2}}{\sqrt{2\pi}} dt, \quad \alpha \in (0, 1).$$

- 3. Homogeneous structures
- 4. Rapid points
- 5. Fractal properties of rapid points
- 6. Recursive properties of rapid points

Note that g is a recursive function, i.e., there is a uniform procedure that outputs $g(\alpha)$ up to arbitrary accuracy using only a finite number of bits of α . We fix a recursive bijection \langle, \rangle from ω^2 to ω . To any $\alpha \in \mathcal{N}$, we associate a sequence $B = (\beta_0, \beta_1, \beta_{jn} : j \geq 1, 0 \leq n < 2^j)$, where the sequence (β_{jn}) is lexicographically ordered with respect to the double indices jn , in such a way that the k th term of the sequence B is given by

$$\alpha_{k0}\alpha_{k1} \cdots .$$

2. Complex oscillations
3. Homogeneous structures
4. Rapid points
5. Fractal properties of rapid points
6. Recursive properties of rapid points

Here, we have written kl instead of $\langle k, l \rangle$. For $1 \leq j < \omega$, $0 \leq n < 2^j$, set $\xi_{jn} = g(\beta_{jn})$; in addition, set $\xi_k = g(\beta_k)$, for $k = 0, 1$. It follows that there is a uniform procedure that computes from $\alpha \in KC$, for each j, n , the number ξ_{jn} up to arbitrary accuracy. For $\alpha \in \mathcal{N}$ and $t \in [0, 1]$ set

$$x_\alpha(t) = \xi_0 \Delta_0(t) + \xi_1 \Delta_1(t) + \sum_{j < \omega} \sum_{n < 2^j} \xi_{jn} \Delta_{jn}(t).$$

It is shown in [F, AM] that, if $\alpha \in KC$, then the series converges and that the function x_α is in fact a complex oscillation. Conversely, for every complex oscillation x , there is a unique KC -string α such that $x = x_\alpha$.

Theorem

If (A_k) is a uniform sequence of $\Sigma_1^0(\mathcal{F})$ sets with $\sum_k W(A_k) < \infty$, then, for each complex oscillation x , it is the case that $x \notin A_k$ for all large values of k .

An analogue for KC -strings of this theorem appears in [3].
