Inductive Definitions with Decidable Atomic Formulas

Anton Setzer *

Department of Mathematics, Uppsala University, P. O. Box 480, S-75106 Uppsala, Sweden. email: setzer@math.uu.se

Abstract. We introduce a type theory for infinitely branching trees, called the theory of free algebras. In this type theory we define an extensional equality based on decidable atomic formulas only. We show, that equality axioms, which add full extensionality to the theory, yield a conservative extension of the (intensional) type theory for formulas having types of level $\leq 1$. Types like nat $\to$ nat and well-founded trees with branching over the natural numbers (Kleene’s O) have this property. We can therefore extract constructive proofs and programs from classical proofs of $\Pi_2$-sentences with this restriction on the types.

1 Introduction

In a series of articles [Be93], [Be95], [BS95a], [BS95b], [BS96], [Sch91], [Sch92], [Sch93a], [Sch93b], [Sch94], [Sch95] Schwichtenberg and Berger have studied the extraction of programs from classical proofs. This method relies on the fact, that in HA$^\omega$ we have no problems, since we can define an extensional equality easily based on decidable prime formulas.

Together with U. Berger, the author has introduced an extension of HA$^\omega$ by adding free algebras or well founded trees with branching over arbitrary types. This extension was necessary in order to treat term systems used for representing for instance non-deterministic terminating computation trees, infinitary term systems or, for implementations of proof theoretical techniques, infinitary formulas and proofs. The latter allows to extract programs from proof theoretical proofs and to work with infinitary logic in type theory. As expected, it turned out that some inductive definition can be defined directly in this theory and that we have the full proof theoretical strength of finitely iterated inductive definitions, as shown by the author ([Se94]).

To make use of this theory for the extraction of programs from classical proofs using equality, such an equality needs to be defined. Since we want to use

* Part of this research was supported by the EU-supported Twinning Project “Proofs and Computation”, Leeds-Munich-Oslo. The research was written up, while the author, at that time based in Munich, was visiting the universities of Stockholm and Uppsala. The author wants to thank P. Martin-Löf for inviting him and making this fruitful visit possible and the logic group in Uppsala for providing such a creative and thoughtful environment.
such an equality in assumptions as well, we need an equality based on decidable prime formulas. In this article we show, that, such an equality can be defined in this extension and that we can prove it is extensional (however, we don’t have all equality axioms available).

The definition of the equality is quite transparent, and uses ideas the author developed for well-ordering proofs in [Se93], [Se95]: We define the type of branches in a free algebra which is a list of indices, where each index potentially leads to a subtree of a term in a free algebra. If $t$ is a term of the free algebra and $b$ is a branch, then we define $t[b]$ to be the subtree reached following this branch to subtrees in $t$. Now $t$ and $t'$ are equal, if at every branch $b$ $t[b]$ and $t'[b]$ are locally equal: the constructors are the same and all labels are the same: $t =_x t' \iff \forall_{\text{branch}(x)}. \text{loc}_x(t[x], t'[x])$. This definition is quite simple, and can be easily implemented.

However, the equality axioms can not be shown. This is no problem, since we can show, that adding such axioms yields a conservative extension of the original theory with respect to formulas using types of level $\leq 1$ only.

The content of this article is as follows: In Sect. 2 we introduce the theory of free algebras FA. In order to make proofs easily, we restrict it to non simultaneous inductive definitions (and get the theory FA$_1$). The equality in FA$_1$ is introduced in Sect. 3 and we show, that we have full extensionality. In Sect. 4 we introduce equality axioms. We then show, that these equality axioms can be cut out: adding the equality axioms yields a conservative extension of FA$_1$ for formulas of type level $\leq 1$. It follows, that adding to FA$_1$ an extensional equality yields a conservative extension for these formulas, and that we can extract constructive proofs and programs from classical proofs of $\Pi_2$-sentences of this level using the extensional equality defined in this article.

Related work. The treatment of strictly positive inductive definitions by introducing labeled trees is used in many type systems. For instance C. Paulin-Mohring has introduced similar inductive structures in the system Coq ([PM93]). The $W$-type of Martin-Löf (see his book [ML84]) is very close to the free algebras, and Petersson and Synek have extended it to labeled trees (very well described in [NPS90], Chap. 16). U. Berger has in [Be94] given a treatment of non strictly positive inductive definitions as well. The treatment of an equality based on atomic prime formulas in such type systems is to our knowledge new.

Elimination of extensionality was first studied by R. Gandy ([Ga56], [Ga59]). Afterwards H. Luckhardt improved these results ([Lu73]). A very good treatment of elimination of extensionality in HA$^\omega$, written by A. Troelstra and based on ideas of W. Howard can be found in [Tr73], pp. 155 ff.

2 Definition of Free Algebras

The idea of free algebras of the strength in consideration is to generalize the principle of free algebras to trees with infinite branching.

The usual definition of a free algebra $\sigma$ is, that we have several constructors $C_i$, each of which has some type $C_i : \alpha_1 \to \cdots \to \alpha_n \to \sigma$.
The semantics of this free algebra is the least set of closed terms, closed under these constructors.

Typical examples are:
- The type $B$ of boolean truth values with constructors true : $B$, false : $B$.
- The type nat having constructors 0 : nat, S : nat $\rightarrow$ nat.
- The type with $k$ elements $\mathbb{N}_k$, having constructors $i_k : \mathbb{N}_k$ for $i < k$.
- If $\alpha_1, \ldots, \alpha_n$ are types, then $\alpha_1 \times \cdots \times \alpha_n$ is defined by one constructor $p_{\alpha_1, \ldots, \alpha_n} : \alpha_1 \rightarrow \cdots \rightarrow \alpha_n \rightarrow (\alpha_1 \times \cdots \times \alpha_n)$.
- $\alpha_1 + \cdots + \alpha_n$ is defined as the type having constructors $i_{\alpha_1, \ldots, \alpha_n, i} : \alpha_i \rightarrow (\alpha_1 + \cdots + \alpha_n)$ ($i = 1, \ldots, n$).
- If $\alpha$ is a type, the type $\text{list}(\alpha)$ is defined by the constructors $\text{Nil}_\alpha : \text{list}(\alpha)$, $\text{Cons}_{\alpha} : \alpha \rightarrow \text{list}(\alpha) \rightarrow \text{list}(\alpha)$.

(We will use these types later and omit the index $\alpha$ in Nil and Cons, and $\alpha_1, \ldots, \alpha_n$ in $p$ and $i$).

In applications we often define several algebras simultaneously. For instance, we can introduce set terms and set formulas by the following definition: Variables are terms, if $r, s$ are terms, then $\{r, s\}$ and $r \cup s$ are set terms, and if $\phi$ is a formula, $a$ a set term, $x$ a variable, then $\{x \in a \mid \phi\}$ is a set term. Formulas are $r \in s$ for $r, s$ set terms, and if $\phi, \psi$ are set terms, $x$ a variable, then $\phi \land \psi$, $\phi \lor \psi$ and $\forall x. \phi$ are formulas. This can be defined (if representing variables as natural numbers) as the free algebra with the following constructors:

- $\text{Var} : \text{nat} \rightarrow \text{term}$.
- $\{\} : \text{term} \rightarrow \text{term} \rightarrow \text{term}$.
- $\cup : \text{term} \rightarrow \text{term} \rightarrow \text{term}$.
- $\text{Separation} : \text{nat} \rightarrow \text{term} \rightarrow \text{for} \rightarrow \text{term}$.
- $\in : \text{term} \rightarrow \text{term} \rightarrow \text{for}$.
- $\land, \lor : \text{for} \rightarrow \text{for} \rightarrow \text{for}$.
- $\forall : \text{nat} \rightarrow \text{for} \rightarrow \text{for}$.

This language has only limited expressiveness: nearly no comprehension is definable yet. In order to express at least restricted comprehension, we are immediately led to the idea of using infinitary formulas and terms. If $\phi_n$ is a formula for $n : \text{nat}$, then $\bigwedge_{n : \text{nat}} \phi_n$ is a formula, and if $a_n$ is a set term for $n : \text{nat}$, then $\bigcup_{n : \text{nat}} a_n$ is a set term, and we need constructors:

- $\bigwedge : (\text{nat} \rightarrow \text{for}) \rightarrow \text{for}$.
- $\bigcup : (\text{nat} \rightarrow \text{term}) \rightarrow \text{term}$.

In order carry out some proof theoretical treatment of set theory in type theory, we need therefore free algebras with infinite branching.

In a theory using free algebras with infinitary branching, we can define for instance Kleene’s O with the constructors $\text{Nil} : O$, $\text{Succ} : O \rightarrow O$, $\text{Lim} : (\text{nat} \rightarrow O) \rightarrow O$.

We can define trees with finite or countable branching, by forming lists of trees $l : \text{tree} \rightarrow \text{list}$ and defining from $l$ a tree $\text{Succtree}(l)$ having as subtrees the elements of the list $l$: 
- Nil : treelist,
- Cons\(_\text{tree}\) : tree → treelist → treelist,
- Succ\(_\text{tree}\) : treelist → tree.
- Lim : (nat → tree) → tree.

The general concept of forming free algebras is, that, if we have constructors, where the type to be defined occurs strictly positive, than we get a new type. The semantics of this type in the term model is the least set of closed terms closed under these constructors. A rigorous definition of free algebras, which does not make use of the adding of new symbols is as follows:

**Definition of the type theory** FA. (a) We inductively define the set of types of FA:

We first define the constructor types together with their free variables:

Let \( x_i \) for \( i \in N \) be special symbols.

If \( \alpha_i, \tau_{i,j} \) are types, \( n \in \omega, \ m_i \in \omega \), then

\[
\alpha_1 \to \cdots \to \alpha_n \\
\to (\tau_{1,1} \to \cdots \to \tau_{1,n_1} \to x_{m_1}) \to \cdots \to (\tau_{k,1} \to \cdots \to \tau_{k,n_k} \to x_{m_k}) \\
\to x_l
\]

is a constructor type with free variables \( \{x_{m_1}, \ldots, x_{m_k}, x_l\} \).

Now, if \( \rho_1, \ldots, \rho_m \) are constructor types, \( \text{FV}(\rho_j) \subset \{x_1, \ldots, x_n\}, 1 \leq j \leq n, \) then

\[
\mu x_{j_1} \cdots \mu x_{j_n} \cdot \mu x_{j_{n+1}} \cdots \mu x_{j_m} (\rho_1, \ldots, \rho_m)
\]

is a type. We call this type a free algebra.

If \( \sigma, \tau \) are types, then \( (\sigma \to \tau) \) is a type.

We have the usual conventions about omitting parenthesis.

(b) We define for every free algebra its **constructors** together with the type of each constructor:

If \( \sigma_j = \mu x_{j_1} \cdots \mu x_{j_n} \cdot \mu x_{j_{n+1}} \cdots \mu x_{j_m} (\rho_1, \ldots, \rho_m), \) then \( C(\sigma_1, \ldots, \sigma_n, i) \) (\( 1 \leq i \leq m \)) are the constructors of \( \sigma_1, \ldots, \sigma_n. \)

If

\[
\rho_i = \alpha_1 \to \cdots \to \alpha_n \\
\to (\tau_{1,1} \to \cdots \to \tau_{1,n_1} \to x_{m_1}) \to \cdots \to (\tau_{k,1} \to \cdots \to \tau_{k,n_k} \to x_{m_k}) \\
\to x_l,
\]

then \( C(\sigma_1, \ldots, \sigma_n, i) \) has type

\[
\alpha_1 \to \cdots \to \alpha_n \\
\to (\tau_{1,1} \to \cdots \to \tau_{1,n_1} \to \sigma_{m_1}) \to \cdots \to (\tau_{k,1} \to \cdots \to \tau_{k,n_k} \to \sigma_{m_k}) \\
\to \sigma_l.
\]
(c) In the following we will introduce free algebras \((\sigma_j)_{1 \leq j \leq n}\) by giving names for \(\sigma_j\) together with names for their constructors \((C_i)_{1 \leq i \leq m}\) and by giving the types \(\rho_i\) of the constructors \(C_i\). In this situation we say, that \((\sigma_j)_{1 \leq j \leq n}\) are defined by the constructors \((C_i: \rho_i)_{1 \leq i \leq m}\).

Functions can now be introduced by recursion over the definition of a free algebra. We could add the recursion operator. However, in a practical implementation in the proof assistant MINLOG, it turned out that one needs to add new functions which remain visible after normalization took place. Therefore we add functions defined by giving their step terms following the inductive definition of the free algebras. These functions will depend on terms.

**Definition 2 of the terms of FA.** (a) We define for every sequence of types 
\(\vec{\gamma} = \gamma_1, \ldots, \gamma_n\) and for simultaneously defined free algebras \(\vec{\sigma} = \sigma_1, \ldots, \sigma_n\) the step type for each constructor:

If \(\sigma_i\) is the free algebra, defined by the constructors \(C_i\) of type
\[
C_i : \alpha_1 \to \cdots \to \alpha_n \\
\to (\tau_{i,1} \to \cdots \to \tau_{i,n_1} \to \sigma_{m_1}) \to \cdots \to (\tau_{i,k,1} \to \cdots \to \tau_{i,k,n_k} \to \sigma_{m_k})
\]

the step type of \(C_i\) with respect to \(\vec{\gamma}\) is
\[
\alpha_1 \to \cdots \to \alpha_n \\
\to (\tau_{i,1} \to \cdots \to \tau_{i,n_1} \to \sigma_{m_1}) \to \cdots \to (\tau_{i,k,1} \to \cdots \to \tau_{i,k,n_k} \to \sigma_{m_k}) \\
\to (\tau_{i,1} \to \cdots \to \tau_{i,n_1} \to \gamma_{m_1}) \to \cdots \to (\tau_{i,k,1} \to \cdots \to \tau_{i,k,n_k} \to \gamma_{m_k})
\]

\(\to \gamma_i\).

(b) Inductive definition of the set of terms together with their type (we write \(t : \sigma\) or \(t : \sigma\), for \(t\) is a term of type \(\sigma\)):

Let for every type \(\sigma\) be infinitely many variables be given. We denote variables of type \(\sigma\) by \(x^\sigma, y^\sigma, \ldots\).

If \(x\) is a variable of type \(\sigma\), then \(x : \sigma\).

If \(s : \sigma \to \rho, t : \sigma\) then \((st) : \rho\).

If \(s : \rho, x\) a variable of type \(\sigma\), then \((\lambda x.s) : \sigma \to \rho\).

If \(C\) is a constructor of type \(\alpha, C : \alpha\).

If \(\sigma_1, \ldots, \sigma_n\) are free algebras simultaneously defined by the constructors \(C_1, \ldots, C_m\), \(\vec{\rho} = \rho_1, \ldots, \rho_n\) is a sequence of types, \(\beta_i\) is the step type of \(C_i\) with respect to \(\vec{\rho}\), \(t_i : \beta_i\), then \(\text{fun}_i(C_1 : t_1, \ldots, C_m : t_m)\) is a term of type \(\sigma_i \to \rho_i\).

(c) We will write \(f(r_1, \ldots, r_n)\) instead of \(f r_1 \cdots r_n\), if \(f : \gamma_1 \to \cdots \gamma_n \to \rho\). This does not cause any confusion with the product of terms, which is written as \(pr_1, \ldots, r_n\) or in the new notation \(p(r_1, \ldots, r_n)\).

(d) We define \(\alpha\)-equality, \(\beta\)-conversion and \(\eta\)-conversion as usual.

Further we define the one-step \(\beta\)-conversion by:
If \( f_i := \text{fun}_i(C_1 : t_1, \ldots, C_m : t_m) \), and 
\( C_i \) of the type as in (a), then 
\[
\begin{align*}
&f_i(C_i(l_1, \ldots, l_m, s_1, \ldots, s_k)) \rightarrow^1 R \\
&t_i(l_1, \ldots, l_m, s_1, \ldots, s_k, \\
&\lambda \lambda x^{T_{x_1}} \cdots \lambda x^{T_{x_n}}. f_{m_1}(s_1(x_1, \ldots, x_n), \ldots, \\
&\lambda \lambda x^{T_{x_1}} \cdots \lambda x^{T_{x_n}}. f_{m_k}(s_k(x_1, \ldots, x_n)))
\end{align*}
\]
for suitable variables \( x_i \).
Further if \( t \rightarrow^1 R \ t' \), then \( s[x := t] \rightarrow R s[x := t'] \).
Let \( \cong \) is the reflexive, symmetric and transitive closure of \( \alpha, \beta, \eta \) conversion and \( \rightarrow R \).
We will in the following identify \( \cong \)-equivalent terms.

(e) We will usually introduce functions by giving their convertibility-rules.

All the examples of types mentioned above can now be defined in FA.

Formulas can now be formed from \( \text{atom}(t) \) for \( t : B \) (so \( \text{atom}(\text{true}) \) is the verum and \( \text{atom} \) \( (\text{false}) \) is the falsum) and we get a logic built on induction over free algebras:

**Definition 3 of the logic in FA.** (a) We define the formulas of FA:
If \( t : B \), then \( \text{atom}(t) \) is an (atomic) formula.
If \( \phi_1, \phi_n \) are formulas, \( x \sigma \) a variable, then \( (\phi_1 \rightarrow \phi_2) \), \( (\phi_1 \land \phi_2) \), \( (\phi_1 \lor \phi_2) \), 
\( (\forall x \sigma. \phi_1) \), \( (\exists x \sigma. \phi_1) \) are formulas.
Note, that we identify \( \equiv \)-equivalent terms.
We will introduce formulas in the form of \( \phi(x) \) for some variable \( x \). After having introduced it in this way, let \( \phi(t) := \phi[x := t] \).

(b) \( \bot := \text{atom}(\text{false}), \quad \neg \phi := \phi \rightarrow \bot \).

(c) The rules of FA are the rules of minimal logic (intuitionistic logic without ex falso quadlibet) with the strong existential quantifier \( \exists^* \), strong disjunction \( \lor^* \), and an axiom \( \text{atom}(\text{true}) \).

Additionally, we have the axioms of induction over free algebras:
Assume \( \sigma_i \) are free algebras, defined by the constructors \( C_1 \cdots C_m \), \( C_i \) is of type as in Def. 2 (a) Then the induction step of \( C_i \) with respect to \( \phi_i(x^{\sigma_1}), \ldots, \phi_n(x^{\sigma_n}) \) is
\[
\forall x^{\alpha_1} \cdots \forall y_1^{\alpha_m} \forall x^{T_{x_1}} \cdots \forall x^{T_{x_n}} \forall y^{T_{y_1}} \cdots \forall y^{T_{y_k}}. \\
(\forall z_1^{T_{x_1}} \cdots \forall z_n^{T_{x_n}}. \phi_1(y(z_1, \ldots, z_n))) \rightarrow \cdots \\
\rightarrow (\forall z_1^{T_{x_1}} \cdots \forall z_n^{T_{x_n}}. \phi_{m_k}(y_k(z_1, \ldots, z_{n_k}))) \\
\rightarrow \phi_i(C_i(x_1, \ldots, x_n, y_1, \ldots, y_k)).
\]

If now \( \psi_1, \ldots, \psi_m \) are the induction steps of \( C_1, \ldots, C_m \) with respect to the formulas \( \phi_i \) as above, then
\[
\psi_1 \rightarrow \cdots \rightarrow \psi_m \rightarrow ((\forall x^{\sigma_1}. \phi_1(x^{\sigma_1})) \land \cdots \land (\forall x^{\sigma_n}. \phi_n(x^{\sigma_n})))
\]
is an axiom of FA.

Proofs in FA are formed by the axioms using the rules. Each proof has a set of free assumptions and a set of free variables. (The free variables are the free (object-)variables in corresponding Curry-Howard terms, i.e. the free variables in the terms used for \( \forall \)-elimination and \( \exists^* \)-introduction, not bound later by \( \forall \)-introduction and \( \exists^* \)-elimination). Closed proofs are proofs that contain no free assumptions and only free variables occurring in the derived formula.\(^2\)

Note, that we have ex falso quodlibet and stability for atomic formulas by induction over \( B \), and therefore ex falso quodlibet for all formulas, and stability for all formulas, which have no occurrence of \( \forall^* \) or \( \exists^* \).

We can simplify the free algebras by reducing simultaneous inductive definitions to non simultaneous ones. This is done by not distinguishing between the types defined before simultaneously:

If \( \sigma_1, \ldots, \sigma_n \) are free algebras, defined by the constructors \( C_1, \ldots, C_m \), let \( \sigma \) be a free algebra defined by the constructors \( C'_1, \ldots, C'_m \), where, if \( C_i \) is of type as in Def. 2 (a),

\[
C'_i : \alpha_1 \to \cdots \to \alpha_k \\
\to (\tau_1,1 \to \cdots \to \tau_{1,n_1} \to \sigma) \to \cdots \to (\tau_r,1 \to \cdots \to \tau_{r,n_r} \to \sigma) \to \sigma .
\]

We define \( f_{\sigma_1,\sigma} : \sigma_i \to \sigma \) by

\[
f_{\sigma_1,\sigma}(C_i(l_1, \ldots, l_k, s_1, \ldots, s_r)) \equiv \\
C'_i(l_1, \ldots, l_k, (\lambda x_1, \cdots, x_{n_1} f_{\sigma_m,\sigma}(s_1(x_1, \ldots, x_{n_1}))), \cdots, \\
(\lambda x_1, \cdots, x_{n_1} f_{\sigma_m,\sigma}(s_1(x_1, \ldots, x_{n_1}))) .
\]

We can reduce the equality on \( \sigma_i \) to the equality on the type \( \sigma \) by applying \( f_{\sigma_1,\sigma} \).

Further, we can replace \( \tau_{i,1} \to \cdots \to \tau_{i,m_i} \to \sigma \) by \( (\tau_{i,1} \times \cdots \times \tau_{i,m_i}) \to \sigma \), if \( m_i \geq 1 \), and define again an embedding. (We could reduce it even more, but this would lead to case distinctions, which are more complicated to deal with).

Therefore, it suffices to study in the following the following set of types:

**Definition 4 of the type theory** FA\(_1\). (a) We define the set of types of FA\(_1\) as a subset of FA:

\(^2\)In the theories usually considered, every type is inhabited and we can replace free variables occurring in the proof and not occurring in free assumptions or the derived formula always by closed terms of the corresponding type, therefore the set of variables can be neglected. FA has empty types, and we have to take care of the free variables. Independently R. Stärk and the unknown referee – we would like to thank both for their comments – pointed out, that there are proofs of \( \bot \) in FA: take the induction axiom \( \forall x \bar{\mathbb{L}}, \bot \), where \( \bar{\mathbb{L}} \) is the empty type with no constructors, and use an \( \forall \)-elimination with the term \( \bar{x} \bar{\mathbb{L}} \). However, this proof depends on the free variable \( \bar{x} \bar{\mathbb{L}} \), is therefore not closed – the consistency of FA is not violated.
Assume $\sigma$ is a free algebra, defined by constructors $C_i$, s.t. each constructor $C_i$ has type

$$\alpha_1^i \rightarrow \cdots \rightarrow \alpha_{m_i}^i \rightarrow (\tau_1^i \rightarrow \sigma) \rightarrow \cdots \rightarrow (\tau_{n_i}^i \rightarrow \sigma) \rightarrow \sigma^{p_i} \rightarrow \sigma,$$

where $\sigma^{p_i} \rightarrow \sigma$ abbreviates $\sigma \rightarrow \cdots \rightarrow \sigma \rightarrow \sigma$ and $\alpha_j^i$, $\tau_j^i$ are types of $\text{FA}_1$.

Then $\sigma$ is a type of $\text{FA}_1$. If $\sigma, \rho$ are types of $\text{FA}_1$, then $(\sigma \rightarrow \rho)$ is a type of $\text{FA}_1$.

(b) If $C_i$ has the type as in (a), the arguments of type $\alpha_j^i$ will be denoted by $l_j$ (for label), of type $\tau_j^i \rightarrow \sigma$ by $s_j$ and the remaining arguments by $t_j$, all possibly with accents etc. We denote the arguments by $t_j$, if we don’t care about the distinction between the groups of arguments. Further let in the following, as arguments of $C_i$, $\vec{l} = (l_1, \ldots, l_{m_i})$, $\vec{s} = (s_1, \ldots, s_{n_i})$, $\vec{t} = (t_1, \ldots, t_{p_i})$, $\vec{l} = (l_1, \ldots, l_{m_i})$, etc.

(c) Terms, formulas of $\text{FA}_1$ are the terms, formulas of $\text{FA}$ which contain only $\text{FA}_1$-types. The rules and axioms of $\text{FA}_1$ are those of $\text{FA}$ which use only $\text{FA}_1$-types.

(d) In the following, if not mentioned differently, $C_i$ will have the type as denoted in Def. (a).

3 Definition of the Equality

As we noted in the introduction, the equality for free algebras is defined as: $t =_\sigma t'$ if $t[b]$ and $t'[b]$ are locally equal, for every branch $b$. Local equality means, that the last constructor is the same and the labels on $t[b]$ and $t'[b]$ are the same. Now the labels at $t[b]$, $t'[b]$ depend on the constructor used. Since we have no dependent types, we need to extract a label, even, if the last constructor does not contain such a label. We deal with this problem by deciding, whether a type is empty or not. If it is empty, we do not need to extract a label of that type. If it is non empty, we have one fixed element, and use, in case the constructor contains no label, this fixed element ($e^\sigma$) as the result of the label-extracting function.

**Definition 5 of $E^\sigma \rightarrow \rho$ and $e^\rho$.** For each type of $\text{FA}_1$ we define, whether it is empty or not, and define if $\sigma$ is non empty, a closed term $e^\sigma$ and if $\sigma$ is empty, for each type $\rho$ a closed term $E^\sigma \rightarrow \rho$ ($E$ stands for ex falso quodlibet), and a proof of $\forall x^\sigma. \phi(x)$ for any formula $\phi(x^\sigma)$:

Case $\sigma$ is a free algebra, defined by constructors $C_i$:

If for one constructor $C_i$ we have for all $j$ $\alpha_j^i$ are non empty, $\tau_j^i$ are empty, $p_i = 0$, then $\sigma$ is non empty. If $i$ is minimal such that $C_i$ is such a constructor, then

$$e^\sigma := C_i(e^{\alpha_1^i}, \ldots, e^{\alpha_{m_i}^i}, E^{\tau_1^i \rightarrow \sigma}, \ldots, E^{\tau_{n_i}^i \rightarrow \sigma}).$$
Otherwise \( \sigma \) is empty, and we define \( \text{E}^{\sigma \rightarrow \rho} \) as the function \( \sigma \rightarrow \rho \) such that if \( C_i \) has a type as above,

\[
\text{E}^{\sigma \rightarrow \rho}(C_i(l_1, \ldots, l_n)) \cong \\
\begin{cases} 
\text{E}^{\alpha_j \rightarrow \rho}(l_j) & \text{if } \alpha_j \text{ is empty, } j \text{ minimal,} \\
\text{E}^{\sigma \rightarrow \rho}(s_j(\epsilon_j)) & \text{otherwise, if } \tau_j \text{ is non empty, } j \text{ minimal,} \\
\text{E}^{\sigma \rightarrow \rho}(t_1) & \text{otherwise.}
\end{cases}
\]

Case \( \sigma \rightarrow \tau \):
If \( \sigma \) is empty, \( \sigma \rightarrow \tau \) is non empty, \( \epsilon^{\sigma \rightarrow \tau} := \text{E}^{\sigma \rightarrow \tau} \).
Otherwise, if \( \tau \) non empty, then \( \sigma \rightarrow \tau \) is non empty, \( \epsilon^{\sigma \rightarrow \tau} := \lambda x^{\sigma}.e^\tau \).
Otherwise \( \sigma \rightarrow \tau \) is empty, \( \text{E}^{\sigma \rightarrow \tau}(x(\sigma)) \).

The proofs of \( \forall x^\sigma.\phi(x) \) for \( \sigma \) empty can be defined in a similar way as \( \text{E}^{\sigma \rightarrow \rho} \), replacing recursion by induction.

We define now the equality on the types. Free algebras, hereditarily built from free algebras with no branching over types, have decidable equality, which we can define as a boolean valued function by recursion over the type:

**Definition 6 of the decidable equality.** We define inductively the set of types \( \sigma \) with decidable equality together with \( \xrightarrow{\sigma} : \sigma \rightarrow \sigma \rightarrow B \) (usually written infix).

If \( \sigma \) is empty, then \( \sigma \) has decidable equality, \( \xrightarrow{\sigma} := \lambda x,y.\text{true} \).
If \( \sigma \) is a non empty free algebra, defined by constructors \( C_i \), such that, for each constructor \( C_i \) of the usual typing \( n_i = 0 \) and for all \( j \alpha_i \) has decidable equality, then \( \sigma \) has decidable equality, and we define \( \xrightarrow{\sigma} \) by

\[
C_i(\vec{l}) \xrightarrow{\sigma} C_j(\vec{l}) \cong \text{false if } i \neq j,
\]

and

\[
C_i(\vec{l}, \vec{t}) \xrightarrow{\sigma} C_i(\vec{l}, \vec{t}) \\
\cong l_i \xrightarrow{\alpha} l_i \land_B \cdots \land_B l_m, \quad \xrightarrow{\alpha} l'_m, \land_B t_1 \xrightarrow{\sigma} t'_1, \land_B \cdots \land_B t_{m}, \quad \xrightarrow{\sigma} t'_{m}.
\]

where \( \land_B \) is the boolean valued function corresponding to the logical connective \( \land \).

The crucial case are free algebras with branching indexed over types. For these trees we define \( \text{index}(\sigma) \) as the union of all types, over which we can reach an immediate subtree. We can define for non empty types its immediate predecessor with respect to an element of \( \text{index}(\sigma) \). \( \text{branch}(\sigma) \) is the list of indices, and by induction over this list we reach every subtree:

**Definition 7 of label, constr, pred, \( r[b] \), index, branch(\sigma), \( \iota, \nu \).** Assume \( \sigma \) is defined by constructors \( C_1, \ldots, C_m \) with the usual typing and non empty.
(a) If $\alpha_i$ is non-empty ($1 \leq i \leq m, 1 \leq j \leq m_i$) we define $\text{label}_{i,j}^\sigma : \sigma \rightarrow \alpha_i$ as

$$\text{label}_{i,j}^\sigma(C_k(I_i, s, \bar{t})) \cong \begin{cases} l_j & \text{if } i = k \\ e_i^j & \text{otherwise.} \end{cases}$$

(b) If $1 \leq i \leq m$, define $\text{constr}_i^\sigma : \sigma \rightarrow B$,

$$\text{constr}_i^\sigma(C_j(I)) \cong \begin{cases} \text{true} & \text{if } i = j \\ \text{false} & \text{otherwise.} \end{cases}$$

(c) Let $\text{index}(\sigma)$ be the free algebra defined by constructors $\iota_i^{\sigma} : \tau_i \rightarrow \text{index}(\sigma)$ ($1 \leq i \leq m, 1 \leq j \leq n_i$), and $\nu_i^{\sigma,j} : \text{index}(\sigma) (1 \leq i \leq m, 1 \leq j \leq p_i)$, i.e. $\text{index}(\sigma)$ is the disjoint union of $\tau_i$, and of a type with one element for $1 \leq i \leq m, 1 \leq j \leq p_i$.

(d) Define the function $\text{pred}^\sigma : \sigma \rightarrow \text{index}(\sigma) \rightarrow \sigma$, assigning the immediate subtree of a tree $t^\sigma$, indexed by $l : \text{index}(\sigma)$ as follows: If $s := C_i(I, \bar{s}, \bar{t})$, then

$$\begin{aligned} \text{pred}^\sigma(s_{i\nu_{i,j}^\sigma(r)}) & \cong \begin{cases} s_j(r) & \text{if } i = i' \\ e_\sigma & \text{otherwise}, \end{cases} \\ \text{pred}^\sigma(s_{i\nu_{i,j}^\sigma}) & \cong \begin{cases} l_j & \text{if } i = i' \\ e_\sigma & \text{otherwise.} \end{cases} \end{aligned}$$

(e) Let $\text{branch}(\sigma) := \text{list}(\text{index}(\sigma))$.

(f) Define $\cdot[t]^\sigma : \sigma \rightarrow \text{branch}(\sigma) \rightarrow \sigma$, written as $s[b]^\sigma$ for $\cdot[t]^\sigma(s, b)$, such that

$$
\begin{aligned} s[\text{Nil}]^\sigma & \cong s \\ s[\text{Cons}(i, b)]^\sigma & \cong \text{pred}_{\sigma}(s, i)[b]. \end{aligned}
$$

We will usually omit the superscript $\sigma$ in all constructors and functions defined above.

Two trees are equal, if the subtrees reached using the same branch are locally equal. Locally equal means, that the constructors are the same and the labels are the same:

**Definition 8 of the equality $\cong_\sigma$ on the type $\sigma$.** The definition is by recursion on definition of $\sigma$.

- Case $\sigma$ has decidable equality. Then $s =_\sigma t := \text{atom}(s =^B t)$.
- Case $\sigma$ is a free algebra with non decidable equality, defined by constructors $C_i$ with the usual typing:
  - If $s : \sigma, t : \sigma$, then $\text{loceq}_\sigma(s, t)$ (local equality) is the formula, which is the conjunction of $\text{label}_{i,j}^\sigma(s) =_{\sigma_j} \text{label}_{i,j}^\sigma(t)$ for $1 \leq i \leq m, 1 \leq j \leq m_i$, $\tau_i$ non empty and $\text{constr}_i(s) =_{B} \text{constr}_i(t)$ ($1 \leq i \leq m$).
  - $s =_\sigma t := \forall x. \text{branch}(\sigma) \cdot \text{loceq}_\sigma(s[x], t[x])$.
- Case $\sigma = \rho \rightarrow \tau$, with non decidable equality: $s =_\sigma t := \forall x. s(x) =_\tau t(x)$.
Theorem 9. We can prove the following in FA₁:

(a) =_σ is reflexive, symmetric and transitive.
(b) If σ is defined by constructors Cᵢ, j ≠ l, then ¬(Cᵢ(ℓ) =_σ Cᵢ(γ)).
(c) If σ is defined by constructors Cᵢ, rᵢ, rᵢ' : σᵢ, then

\[ Cᵢ(r₁, \ldots, rₖ) =_σ Cᵢ(r₁', \ldots, rₖ') \iff (r₁ =_σ r₁' \land \cdots \land rₖ =_σ rₖ') \ . \]

Proof. (a) Immediate by Meta-induction on the types.
(b) Trivial.
(c) The case, where σ has decidable equality is immediate. Non decidable case:
Let s := Cᵢ(ℓ) =: Cᵢ(ℓ, s, ℓ), s' := Cᵢ(ℓ') =: Cᵢ(ℓ', s', ℓ'). Then
loceq(s[Nil], s'[Nil]) iff \( l_j = l'_j \) for \( 1 \leq j \leq m_i \).
If \( u : τ_j^i, x : \text{branch}(σ) \), then

\[ \text{loceq}(s[\text{Cons}(i_i^j(u), x)], s'[\text{Cons}(i_i^j(u), x)]) \iff \text{loceq}((s_j(u))[x], (s'_j(u))[x]) \]

for \( k \neq i \),

\[ \text{loceq}(s[\text{Cons}(i_k,j(u), x)], s'[\text{Cons}(i_k,j(u), x)]) \iff \text{loceq}(e^σ[x], e'^σ[x]) \]

where the right side holds by reflexivity. We have similar statements for \( s[\text{Cons}(ν_k,j, x)] \) and it follows

\[ \forall x^{\text{branch}(σ)} \text{loceq}(s[x], s'[x]) \]
\[ \iff \bigwedge_{1 \leq j \leq m_i} l_j =_{σ_j} l'_j \land \bigwedge_{1 \leq j \leq n_i} \forall u^{τ_j^i} \forall x^{\text{branch}(σ)} \text{loceq}(s_j(u)[x], s'_j(u)[x]) \land \]
\[ \bigwedge_{1 \leq j \leq p_i} \forall x^{\text{branch}(σ)} \text{loceq}(t_j[x], t'_j[x]) \]
\[ \iff \ell = \ell' \land \bar{s} = \bar{s}' \land \ell = \ell' \ . \]

4 Equality Axioms

In order to make use of our equality, we need equality axioms, which are not provable in FA₁ (or at least this should be the case by extending proofs for HA°°). We show, that FA₁ - Eq is conservative over FA₁ for formulas with no occurrences of types of level ≥ 2 (we could allow negative occurrences of \( \forall x^σ \) and positive occurrences of \( \exists x^σ \) for level(σ) ≥ 2).

Definition 10 of FA₁ - Eq. Let FA₁ - Eq be defined as FA₁, but with the additional axioms for the extensional equality:
For any types \( ρ, σ \):

\[ \forall x^ρ, y^ρ, z^{ρ→σ} x =_ρ y \rightarrow z(x) =_σ z(y) . \]
For proving our conservativity result, we will follow the approach we found in [Sch94], pp. 52 – 53 for the case of the typed lambda calculus and which again goes back to [Tr73], pp. 155 ff., and adapt it to the situation of free algebras.

The method used, is to define the formula \( r \sim_\sigma s \) meaning: \( r \) and \( s \) are hereditarily extensional equal. If \( \phi^- \) is the result of restricting a quantifier \( \forall x \) and \( \exists x \) to \( x \sim x \), we can show, that if \( FA_1 \models \text{Eq}\downarrow \phi \), then \( FA_1 \models \phi^- \). Now for formulas having the restriction to types of level \( \leq 1 \), \( \phi \leftrightarrow \phi^- \) is provable in \( FA_1 \) and we are done.

**Definition 11 of \( \sim \).** We define \( r \sim_\sigma s \) for every type \( \sigma \), and \( r, s : \sigma \) by recursion on the definition of the types:

- If \( \sigma \) has decidable equality, then \( r \sim_\sigma s := r =_\sigma s \).
- Assume now \( \sigma \) has a non decidable equality.
- If \( \sigma \) is a free algebra defined by constructors \( C_i \) with the usual typing, then let \( \text{loceq}_\sigma^\sim(s, t) \) be the conjunction of \( \text{label}^\sim_i(s) \sim \text{label}^\sim_{i,j}(t) \) for \( 1 \leq i \leq m_i \), \( 1 \leq j \leq m_i \), \( \tau_i \) non empty and \( \text{constr}(s) \sim \text{constr}(t) \) (1 \( \leq i \leq m_i \)).

\[
s \sim_\sigma t := \forall x^{\text{branch}(\sigma)}, y^{\text{branch}(\sigma)}. x \sim_{\text{branch}(\sigma)} y \rightarrow \text{loceq}_\sigma^\sim(s[x], t[y]) .
\]

If \( \sigma = \rho \rightarrow \tau \), then

\[
t \sim_\sigma t' := (\forall x^\rho, y^\rho. x \sim_\rho y \rightarrow tx \sim_\tau t'y) .
\]

**Remark.** More precisely, in the above definition we have to proceed as follows, since \( \text{branch}(\sigma) \) is in general more complex than \( \sigma \):
index(index(\sigma)) has no constructors, therefore decidable equality, therefore as well \( \text{branch}(\text{index}(\sigma)) = \text{list}(\text{index}(\text{index}(\sigma))) \), and then we can define

\( \sim_{\text{branch}(\text{index}(\sigma))} \) and, using \( \sim_{\tau_i, j, 1, \text{index}(\sigma)} \).

index(\text{branch}(\sigma)) has only constructors \( \text{index}(\text{branch}(\sigma)) \) : \( \text{index}(\text{branch}(\sigma)) \), therefore decidable equality, therefore as well \( \text{branch}(\text{branch}(\sigma)) \), and we get a definition of \( \sim_{\text{branch}(\text{branch}(\sigma))} \) and, using \( \sim_{\text{index}(\text{branch}(\sigma))} \) as well of \( \sim_{\text{branch}(\sigma)} \). Now we can define \( \sim_\sigma \).

**Lemma 12.** \( \sim_\sigma \) is symmetric and transitive.\(^3\)

**Proof.** Easy.

**Definition 13 of level of types, N- and P-formulas.** (a) We define the level of types \( \text{level}(\sigma) \) by recursion on the inductive definition of the type \( \sigma \):

- If \( \sigma \) has decidable equality, then \( \text{level}(\sigma) := 0 \).
- If \( \sigma \) is a free algebra with non decidable equality, defined by the constructors \( C_i \), typed as usual, then

\[
\text{level}(\sigma) := \max \{ \text{level}(\alpha^\sigma_i) \mid 1 \leq i \leq m_i, 1 \leq j \leq m_i \} \\
\cup \{ \text{level}(\tau^\sigma_i) + 1 \mid 1 \leq i \leq m_i, 1 \leq j \leq n_i \} .
\]

\(^3\) Note that reflexivity of \( \sim_\sigma \) is not provable. By symmetry and transitivity follows \( x \sim_\sigma y \rightarrow x \sim_\sigma x \).
If $\sigma = \rho \rightarrow \tau$ with non decidable equality, then
\[
\text{level}(\sigma) := \max\{\text{level}(\rho) + 1, \text{level}(\tau)\}.
\]
(b) We define the $P$- and $N$-formulas:
atom($r$) is a P and an N-formula.
- If $\phi, \psi$ are P (N)-formulas, then $\phi \land \psi$, $\phi \lor \psi$ are P (N)-formulas.
- If $\phi$ is a P (N)-formula, then $\psi \rightarrow \phi$ is a P (N)-formula.
- If $\phi$ is a P-formula then $\exists x^\sigma \phi$ is a P-formula, and, if level($\sigma$) \leq 1, $\forall x^\sigma \phi$ is a P-formula.
- If $\phi$ is an N-formula then $\forall x^\sigma \phi$ is an N-formula, and, if level($\sigma$) \leq 1, $\exists x^\sigma \phi$ is an N-formula.

Lemma 14. If $\sigma$ has decidable equality, $\tau$ is a type, then
$\forall x^\sigma, y^\sigma.x =_\sigma y \rightarrow \forall f^\sigma \rightarrow \tau.((\forall z^\sigma.f(z) _\sigma = f(z)) \rightarrow f(x) _\sigma = f(y))$.

Proof by Meta-induction on the definition of the types. If $\sigma$ is empty, this follows immediately.

If $\sigma$ is a free algebra, defined the constructors $C_i$ with usual typing, $\alpha^i_j$ have decidable equality, $n_i = 0$, we show the assertion by induction on $x^\sigma$, side-induction on $y^\sigma$.

Assume $x \equiv C_i(l_i, t_i)$, $l_i = \alpha^i_j$, $t_i = _\sigma t_i$ and assume the assertion for $t_i$.

Let
\[
g_j := \lambda x^{\alpha^i_j}. f(C_i(l_i, \ldots, l_{j-1}, x, l_{j+1}, \ldots, l_{m_i}, t_i, \ldots, t_p)),
\]
\[
h_j := \lambda x^{\alpha^i_j}. f(C_i(l_i', \ldots, l_{j-1}', x, l_{j+1}', \ldots, l_{m_i}, t_i, \ldots, t_p)).
\]

By Meta-II we have $g_j(l_j) _\tau = g_j(l_j')$ and by IH for $t_j$, $h_j(t_j) _\tau = h_j(t_j')$. By the transitivity of $\sim$ follows the assertion.

It causes slight technical problems that $r _\sim s$ depends on $r _{\text{branch}(\sigma)} s$, where branch($\sigma$) is in general more complicated than $\sigma$. In the following lemma we overcome this difficulty:

Lemma 15. (a) Assume $\sigma$ with non decidable equality, $\sigma$ be defined by constructors $C_i$ with the usual typing, $e^{\alpha^i_j} _\sim e^{\alpha_j}$, if $\alpha^i_j$ is non empty. Then
$\forall x^{\text{branch}(\sigma)}. \text{localeq}^\sim(e^\sigma[x], e^\sigma)$.

(b) For all non empty types $\sigma$, $e^\sigma _\sim e^\sigma$, and for all empty types $\sigma$ and all types $\rho$, $E^{\sigma \rightarrow \rho} _\sim E^{\sigma \rightarrow \rho}$.

(c) If branch($\sigma$) has decidable equality, then
$\forall r _\sim r' \leftrightarrow \forall x^{\text{branch}(\sigma)}. \text{localeq}^\sim(r[x], r'[x])$.

(d) Assume $\sigma$ defined by constructors $C_i$ with usual typing. Then
$\text{\iota}_{i,j}(r) _{\text{index}(\sigma)} \iota_{i',j'}(r')$, if $i \neq i'$ \lor $j \neq j'$,
$\nu_{i,j}(r) _{\text{index}(\sigma)} \nu_{i',j'}(r')$, if $i \neq i'$ \lor $j \neq j'$.
(e) Assume σ defined by constructors $C_i$ with usual typing. Then

$$\text{Nil} \sim_{\text{branch}(\sigma)} \text{Nil} \neq_{\text{branch}(\sigma)} \text{Cons}(i, b), \quad \text{Cons}(i, b) \sim_{\text{branch}(\sigma)} \text{Cons}(i', b') \leftrightarrow i \sim_{\text{index}(\sigma)} i' \land b \sim_{\text{branch}(\sigma)} b'. \quad \text{Proof.}$$

(a) $e^\sigma = C_i(e^{i_1}, \ldots, e^{i_{m_i}}, E^{i_{m_i} \rightarrow \sigma}_1, \ldots, E^{i_{m_i} \rightarrow \sigma}_{t_i}), \alpha_j$ non empty, $\tau_j$ empty.

Induction on $x_{\text{branch}(\sigma)}$.

If $x \equiv \text{Nil}$, the assertion is trivial.

If $x \equiv \text{Cons}(i, b)$, then if $i \equiv i_j^1(s)$ with $s : \tau_j^1$, then by $\tau_j^1$ empty we get the assertion. Otherwise $e[x] \cong e[b]$ and the assertion follows by IH.

(b) $E^{\sigma \rightarrow \tau} \sim E^{\sigma \rightarrow \tau}$ follows from the emptiness of $\sigma$.

Proof of $e_{\sigma} \sim e_{\sigma}$ by Meta-induction on the definition of types:

If $\sigma$ has decidable equality, the assertion follows by reflectivity of $=_{\sigma}$.

If $\sigma$ is a free algebra, the assertion follows by the symmetry and transitivity of $=_{\sigma}$ and (a).

If $\sigma = \rho \rightarrow \tau$, $\rho$ is empty, $e^{\sigma} \equiv E^{\rho \rightarrow \tau} \sim E^{\rho \rightarrow \tau} \equiv e^{\sigma}$, and if $\rho$ is non empty, $\tau$ is non empty, follows for all $x, y : \rho : e^{\sigma}(x) \equiv e^{\tau}(x) \sim e^{\tau}(y)$.

(c) $\sim_{\text{branch}(\sigma)}$ follows by the reflectivity of $\sim_{\text{branch}(\sigma)} \equiv_{\text{branch}(\sigma)}$.

"←": Assume $x \sim y$, i.e. $x = y$, $\forall x_{\text{branch}(\sigma)}. \text{loceq}_{\sim} (r[x], r'[y])$. Then

$$\forall x_{\text{branch}(\sigma)}. \text{label}_{i,j}(r[x]) \sim \text{label}_{i,j}(r'[y]),$$

by Lemma 14

$$\text{label}_{i,j}(r[x]) \sim \text{label}_{i,j}(r'[y]).$$

Similarly constr$_i(r[x]) \sim$ constr$_i(r'[y])$, $\text{loceq}_{\sim} (r[x], r'[y])$.

(d) and (e) follow using (b) and (c), since the types branch(index(\sigma)) and branch(branch(\sigma)) have decidable equality.

Now we are ready, to characterize $\sim_{\sigma}$ similarly to the characterization of $=_{\sigma}$ before:

**Lemma 16.** Assume $\sigma$ is a free algebra defined by constructors $C_i$ with usual typing.

(a) If $i \neq j$, then $C_i(\vec{r}) \neq_{\sigma} C_j(\vec{r})$.

(b) Let $r := C_i(\vec{l}, \vec{s}, \vec{t}), r' := C_i(\vec{l}', \vec{s}', \vec{t}')$. Then

$$r \sim_{\sigma} r' \Leftrightarrow \bigwedge_{j=1}^{m_i} l_j \sim l'_j \land \bigwedge_{j=1}^{n_i} s_j \sim s'_j \land \bigwedge_{j=1}^{p_i} t_j \sim t'_j. \quad \text{Proof.}$$

If $\sigma$ has decidable equality the assertions are easy.

(a): easy.

(b): "→": Nil $\sim$ Nil, $\text{loceq}^{-}(r[\text{Nil}], r'[\text{Nil}])$, $l_i \sim l_i$. Further, if $b \sim_{\text{branch}(\sigma)} b'$, $y \sim_{\tau_j^1} y'$, then $\text{Cons}(i_j, y), b \sim \text{Cons}(i_j, y'), b', r[\text{Cons}(i_j, y), b] \cong (s_j(y))[b], \text{loceq}^{-}(r[\text{Cons}(i_j, y), b], r'[\text{Cons}(i_j, y'), b')], \text{loceq}^{-}(s_j(y)[b], s'_j(y)[b']), s_j(y) \sim s'_j(y'), s_j \sim s'_j$, similarly follows $t_j \sim t'_j$.

"←": By induction on branch(\sigma) we show $x \sim y \rightarrow \text{loceq}^{-}(r[x], r'[y])$.
Lemma 17. If level(σ) ≤ 1, then ∀x⁰.x ∼ x.

Proof by Meta-induction on the types. If σ has decidable equality, this is trivial. If σ is a free algebra defined by constructors C_i with usual typing, we use induction on x : σ, and have in case x = C_i(l_1, ..., l_{m_i}, s_1, ..., s_{n_i}, x), l_i ∼ l_i by Meta-III, by IH ∀x⁰.l_j ∼ l_j(x), therefore by Lemma 14 s_j ∼ s_j, by IH t_j ∼ t_j, by Lemma 16 (b) x ∼ x.

If σ = ρ → τ follows for x : σ, by IH ∀y⁰.x(y) ∼ x(y) and by Lemma 14 x ∼ x.

Lemma 18. If r(ξ) := r[ξ := ξ], FV(r) ⊆ {z_1, ..., z_n}.
Then ∀ξ, ξ' ∼ ξ. FV(r(ξ)) ⊆ {z_1, ..., z_n}.
Proof by Meta-induction on the definition of the terms. Case r = C_i constructor: by Lemma 16 (b).
Case r = f⁰ → τ function defined from step terms t_i.
Assume ξ, ξ' ∼ ξ and let g := f[ξ := ξ], g' := f[ξ := ξ'], t_i := r_i[ξ := ξ],

We show ∀x⁰.x⁰ ∼ y → g(x) ∼ g'(y) by induction on x, y : σ.
Case x = C_i(t_i, ξ, ξ'), y = C_i(t_i, ξ, ξ').

Definition 19 of φ⁻ and ~. (a) Let for φ a formula, φ⁻ be the result of binding all quantifiers ∀, ∃ by ~: (∀x.φ)⁻ := ∀x.x ∼ φ⁻, (∃x.φ)⁻ := ∃x.x ∼ x ∧ φ⁻, and for other formula constructions φ⁻ is the result of applying this operation to its components.
(b) r ∼ ~ := (r = s)⁻.

Lemma 20. (a) Lemmata 15 and 16 follow with ~ replaced by ~', looceq(σ, r, s) replaced by (looceq(σ, r, s))⁻.
(b) ∀x⁰.y⁰.x ∼ x ∼ y → y ∼ (x ∼ y → (x = y)⁻).
(c) ∀x, y, z x ⇒ y ⇒ (z(x) ⇒ z(y))⁻.

Proof. (a) easy.
(b) Meta-induction on the definition of the types. If σ has decidable equality, the assertion is trivial. If σ is a free algebra defined by constructors C_i, show the assertion by induction on x, y : σ. If x = C_i(r_1, ..., r_{n_i}), y = C_i(r'_1, ..., r'_{n_i}),
x ∼ x, y ∼ y, then r_i ∼ r_i, r_i' ∼ r_i',

using Meta-III and IH.
If σ = ρ → τ the assertion is easy.
(c): by (b).
Theorem 21. If $\text{FA}_1 - \text{Eq} \vdash \phi$, $\text{FV}(\phi) \subset \mathcal{E}$, then $\text{FA}_1 \vdash \forall \mathcal{E}. \mathcal{E} \sim \mathcal{E} \rightarrow \phi^\sim$.

Proof by Meta-induction on the derivation. The logical rules are easy (for the rules $\forall$-elimination and $\exists^*$-introduction note that by lemma 18 for the term $r$ used we have $\forall \mathcal{E}. \mathcal{E} \sim \mathcal{E} \rightarrow r \sim r$). The extensionality axiom was just treated. For every induction axiom $\psi$ of a formula $\phi(x)$ we have $\psi^\sim$, since using Lemma 16 (b), from the premise of $\psi^\sim$ we can derive the step terms for the induction axiom for $\phi'(x) := \mathcal{E} \sim x \rightarrow \phi^\sim(x)$.

Theorem 22. (a) $\text{FA}_1 - \text{Eq}$ is a conservative extension for $\text{FA}_1$ for $P$-formulas:
If $\phi$ is a closed $P$-formula, $\text{FA}_1 - \text{Eq} \vdash \phi$, then $\text{FA}_1 \vdash \phi$.
(b) Adding to $\text{FA}_1$ an extensional equality yields a conservative extension of $\text{FA}_1$ for $P$-formulas
(c) Especially this holds for formulas containing only types of level $\leq 1$.

Proof. From $\text{FA}_1 - \text{Eq} \vdash \phi$ follows $\text{FA}_1 \vdash \phi^\sim$. Now using Lemma 17 follows, if $\psi$ is an $N$-formula, $\text{FV}(\psi) \subset \{\mathcal{E}\}$, $\text{FA}_1 \vdash \forall \mathcal{E}. \mathcal{E} \sim \mathcal{E} \rightarrow \psi \rightarrow \psi^\sim$ and if $\psi$ is a $P$-formula, then $\text{FA}_1 \vdash \forall \mathcal{E}. \mathcal{E} \sim \mathcal{E} \rightarrow \psi^\sim \rightarrow \psi$. Therefore we get $\text{FA}_1 \vdash \phi$.
(b): by (a), since we can interpret $\text{FA}_1$ extended by axioms for an extensional equality in $\text{FA}_1 + \text{Eq}$.
